Business Problem And Project Overview

Project overview

The project is to analyze how can Airbnb hosts and stakeholders understand listing performance and evaluate pricing decisions to maximize revenue

The Power BI dashboard integrates listing, calendar, host, and review data to evaluate pricing, availability, and performance metrics.

We analyze Airbnb data for Antwerp and use interactive What-If parameters to simulate pricing and occupancy scenarios, enabling informed, data-driven revenue decisions without machine learning.

Three teal semi-circles of increasing size are arranged horizontally on the left side of the slide. The largest semi-circle is on the right, and the text 'Data Sources' is overlaid on its right edge.

Data Sources

DATA SOURCES

Listings

Serves as the primary fact table for analyzing listing characteristics and price distribution.

Hosts

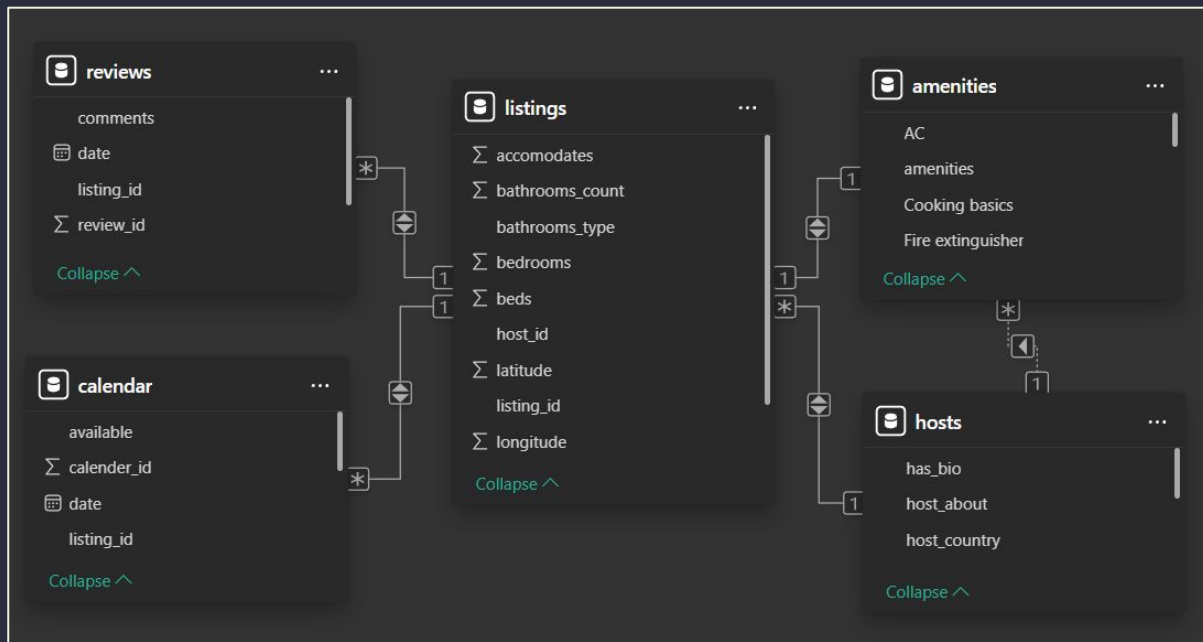

Supports host-level analysis including experience, profile data, and performance.

Reviews

Used to assess listing popularity, host engagement, and review trends.

Calendar

Used to calculate availability rates, active days, and projected revenue scenarios.

Three teal semi-circles of increasing size are arranged horizontally on the left side of the slide. The first is the smallest, the second is medium, and the third is the largest, partially overlapping the text.

Data Cleaning

CALENDAR

The Calendar table contains **3,19,192** records with day-level availability and pricing data for each listing.

Date formats were standardized, availability values converted to **True/False** for clarity, price fields converted and rounded to two decimal places and missing prices were imputed using average price to improve analytical visibility.

HOST

The Hosts table was cleaned by standardizing the host_since date format and deriving **host tenure (in years)** to measure hosting experience.

Host location was further bifurcated to extract geographic attributes such as **country**, enabling cleaner location-based analysis and filtering.

LISTING

The Listings table required minimal data-type changes, as most fields were already in **usable formats**.

The bathroom information was split into structured components to enable clearer analysis of property features and improve comparability across listings.

REVIEWS

The Reviews table was cleaned by converting review dates into a standard date format.

This enables **accurate time-based analysis** of review trends and aggregation at listing and host levels.

AMENITIES

A **new table was created** by separating the multi-valued amenities field from the Listings table.

We created boolean indicators for frequently occurring amenities and calculated an amenity count per listing. The complete amenities list was normalized into a separate table to maintain scalability while avoiding an overly wide table.

Core DAX Measures and Logic

Key Business Metrics

Average Price	Mean nightly price across all available dates
Total Nights	Total calendar days in scope
Available Nights	Nights marked as available for booking
Availability Rate	Ratio of available nights to total nights
Total Listings	Distinct count of active Airbnb listings

Core DAX Measures

Average Price = AVERAGE (calendar[price])

Total Nights = COUNT (calendar[date])

Available Nights =
CALCULATE (
COUNT (calendar[date]),
calendar[available] = TRUE ()
)

Availability Rate =
DIVIDE (
[Available Nights],
[Total Nights]
)

Total Listings =
DISTINCTCOUNT (listings[listing_id])

Key Scenario Metrics

Scenario Price

Adjusted nightly price after seasonality

Projected Booked Nights

Expected bookings volume

Projected Revenue

Scenario-based revenue

Baseline Revenue

Revenue under current pricing

Revenue Delta

Scenario impact vs baseline

Listing Projected Revenue

Aggregated scenario revenue by listing

Listing-Level Revenue Calculation

1. Calculates revenue for each listing individually
2. Aggregates listing revenues to total revenue
3. **Enables:**
 - a. Top revenue listings analysis
 - b. Host-wise revenue comparison

Scenario Measures

Scenario Price = Average Price × Seasonal Multiplier

Projected Booked Nights = Available Nights × Occupancy Rate

Projected Revenue = Scenario Price × Projected Booked Nights

Baseline Revenue = Average Price × Available Nights

Revenue Delta = Projected Revenue – Baseline Revenue

Listing projected revenue = SUMX (VALUES (listings[listing_id]), [scenario price] * [projected booked nights])

Scenario Analysis and Logic

(What-if Parameters)

Calculations based on Occupancy Rate

$$\text{Occupancy Rate} = \frac{\text{Booked Nights}}{\text{Available Nights}}$$

Aspect	Value / Rule	Reasoning	Business Interpretation
Definition	Booked Nights ÷ Available Nights	Occupancy represents a ratio, not an absolute count	Measures how efficiently available inventory is utilized
Minimum Value	0	Zero bookings across all available nights	Worst-case scenario, off-season demand, or property unavailable
Maximum Value	1 (Power BI practical limit: 0.95)	1 indicates all available nights are booked; Power BI caps at 0.95	95% occupancy is more realistic than 100% in real markets
Increment	0.05 (5%)	Allows smooth slider interaction and intuitive adjustment	Aligns with business thinking (e.g., "increase occupancy by 5%")
Default Value	0.7 (70%)	Based on typical urban Airbnb occupancy (60–75%)	Represents stable, most-likely demand scenario

Seasonal Multiplier – Parameter Design Explanation

Off-Season

Peak
Season

0.60(60%)

Seasonal Multiplier -
0.80(20% Discount)

0.90(90%)

Seasonal Multiplier -
1.30(30% Price Hike)

Key Insights & Recommendations

Source

Overview – Pricing, Availability & Revenue

Listing Analysis – Revenue & Geography

Scenario Insights – Pricing Sensitivity

Reviews & Amenities

Hosts & Power Sellers

Key Insights

- Revenue more sensitive to occupancy & seasonality
- Strong seasonality: Mar–Jun peak, Dec weakest
- Top 10 listings drive outsized revenue
- Entire homes dominate high revenue
- Central Antwerp drives most demand
- Entire homes show higher price tolerance
- Scenario revenue < baseline → conservative model
- Amenity count ≠ guaranteed revenue
- Reviews & host tenure correlate strongly with revenue
- ~50% hosts lack profile bios
- One professional host dominates listings & reviews
- Long tail of small, casual hosts
- Entire homes heavily outnumber other types

Business Recommendations

- Focus on occupancy uplift over price hikes
- Dynamic pricing: higher in peak, discounts in Q4
- Reduce dependency by uplifting mid/low performers
- Incentivize amenity upgrades for mid-tier listings
- Apply location-based pricing premiums
- Apply aggressive pricing only to tolerant segments
- Keep shared rooms competitively priced
- Use scenario sliders for risk-aware planning
- Push profile completion (bios, photos)
- Encourage review generation post-stay
- Prioritize experience quality over amenity volume
- Segment hosts: professional vs casual
- Offer portfolio tools for large hosts
- Education & automation for small hosts

Next steps

Deploy Occupancy-First Pricing Strategy

Shift pricing decisions to prioritize occupancy uplift over blanket price increases, especially in off-peak months where underutilized inventory presents immediate revenue upside.

Implement Seasonal Playbooks by Segment

Define clear pricing and promotion strategies by month and listing type (entire homes vs shared rooms), with aggressive optimization during Mar–Jun and defensive tactics in Q4.

Target Revenue Concentration Risk

Reduce dependency on top-performing listings by actively uplifting mid-tier and lower-tier listings through pricing guidance, amenity improvements, and visibility boosts.

Differentiate Host Engagement Models

Segment hosts into professional and casual cohorts and deploy tailored tools—advanced revenue optimization for large operators and onboarding, automation, and education for smaller hosts.
